<b>9</b>	<b>License</b>	<b>21</b>

Tailon is a self-hosted web application for looking at and searching through log files. It is little more than a fancy web wrapper around the following commands:

```
tail -f  
tail -f | grep  
tail -f | awk  
tail -f | sed
```

## CHAPTER 1

## Screenshots

```

/var/log/application.log  Tail  mode "tail" does not accept any input

## CHAPTER 2

---

### Installation

---

The latest stable version of tailon can be installed from [pypi](#):

```
$ pip install tailon
```

The development version is available on [github](#) and can also be installed with the help of pip:

```
$ pip install git+git://github.com/gvalkov/tailon.git
```

Tailon works with Python 2.7 and newer. Using it with Python  $\geq 3.3$  is encouraged.

### 3.1 Tailon

Tailon is a command-line tool that spawns a local http server that serves your logfiles. It can be configured entirely from its command-line interface or through the convenience of a yaml config file.

To get started, run tailon with the list of files that you wish to monitor:

```
$ tailon -f /var/log/nginx/* /var/log/apache/{access,error}.log
```

If at least one of the specified files is readable, tailon will start listening on <http://localhost:8080>.

Tailon's server-side functionality is summarized entirely in its help message:

```
Usage: tailon [-c path] [-f path [path ...]] [-h] [-d] [-v]
           [--output-encoding enc] [--input-encoding enc] [-b addr:port]
           [-r path] [-p type] [-u user:pass] [-a] [-f] [-t num]
           [-m [cmd [cmd ...]]] [--no-wrap-lines]

Tailon is a web app for looking at and searching through log files.

Required options:
  -c, --config path          yaml config file
  -f, --files path [path ...] list of files or file wildcards to expose

General options:
  -h, --help                 show this help message and exit
  -d, --debug                show debug messages
  -v, --version              show program's version number and exit
  --output-encoding enc      encoding for output
  --input-encoding enc       encoding for input and output (default utf8)

Server options:
  -b, --bind addr:port       listen on the specified address and port
  -r, --relative-root path   web app root path
```

```
-p, --http-auth type          enable http authentication (digest or basic)
-u, --user user:pass         http authentication username and password
-a, --allow-transfers         allow log file downloads
-F, --follow-names           allow tailing of not-yet-existent files
-t, --tail-lines num         number of lines to tail initially
-m, --commands [cmd [cmd ...]] allowed commands (default: tail grep awk)
```

User-interface options:

```
--no-wrap-lines              initial line-wrapping state (default: true)
```

Example config file:

```
bind: 0.0.0.0:8080           # address and port to bind on
allow-transfers: true        # allow log file downloads
follow-names: false          # allow tailing of not-yet-existent files
relative-root: /tailon      # web app root path (default: '')
commands: [tail, grep]      # allowed commands
tail-lines: 10               # number of lines to tail initially
wrap-lines: true             # initial line-wrapping state
```

files:

```
- '/var/log/messages'
- '/var/log/nginx/*.log'
- '/var/log/xorg.[0-10].log'
- '/var/log/nginx/'        # all files in this directory
- 'cron':                  # it's possible to add sub-sections
  - '/var/log/cron*'
```

```
http-auth: basic            # enable authentication (optional)
users:                      # password access (optional)
  user1: pass1
```

Example command-line:

```
tailon -f /var/log/messages /var/log/debug -m tail
tailon -f '/var/log/cron*' -a -b localhost:8080
tailon -f /var/log/ -p basic -u user1:pass1 -u user2:pass2
tailon -c config.yaml -d
```

Please note that if the file list includes wildcard characters, they will be expanded only once at server-start time.

---

## Reverse proxy configuration

---

### 4.1 Nginx

1. Run `tailon`, binding it to `localhost` and specifying a relative root of your liking. For example:

```
$ tailon -f /var/log/nginx/* -b localhost:8084 -r '/tailon/'
```

2. Add the following location directives to `nginx.conf`:

```
location /tailon/ws {
    proxy_pass http://localhost:8084/tailon/ws;
    proxy_http_version 1.1;
    proxy_set_header Upgrade $http_upgrade;
    proxy_set_header Connection "upgrade";
}

location /tailon {
    proxy_pass http://localhost:8084;
}
```

Tailon runs commands on the server it is installed on. While commands that accept a script argument (such as `awk`, `sed` and `grep`) should be invulnerable to shell injection, they may still allow for arbitrary command execution and unrestricted access to the filesystem.

To clarify this point, consider the following input to the `sed` command:

```
s/a/b'; cat /etc/secrets
```

This will result in an error, as tailon does not invoke commands through a shell. On the other hand, the following command is a perfectly valid `sed` script that has the same effect as the above attempt for shell injection:

```
r /etc/secrets
```

The default set of enabled commands - `tail`, `grep` and `awk` - should be safe to use. GNU `awk` is run in `sandbox` mode, which prevents scripts from accessing your system, either through the `system()` builtin or by using input redirection.

By default, tailon is accessible to anyone who knows the server address and port. One way to restrict access is by using the built-in basic and digest http authentication. This can be enabled on the command-line with:

```
$ tailon -p basic -u joe:secret1 -u bob:secret2
$ tailon -p digest -u joe:secret1 -u bob:secret2
```

## CHAPTER 6

---

### Development

---

Code, bug reports and feature requests are kindly accepted on tailon's [github](#) page. Please refer to the development document for more information on developing tailon.
